Immunization are mostly stated as a less risky and easier way to become immune to any particular disease than risking a milder form of disease itself.

Immunization

Active immunization can occur naturally when a person comes in contact with (for example) a microbe. The immune system will eventually create antibodies or other defenses against the microbe. The next time, the immune response against microbe can be very efficient, this is the case in many of the childhood infections that a person only contracts with once, but then is immune.

One hundred years ago infectious diseases were one of the leading deaths around the world. In Canada they now cause less than 5% of all deaths all, because of immunization programs across Canada.
